Substituted methylene amide derivatives as Modulators of Protein Tyrosine Phosphatases (PTPs)

Field of the invention

The present invention is related to substituted methylene amide derivatives of formula (I), in particular for the treatment and/or prevention of metabolic disorders mediated by insulin resistance or hyperglycemia, comprising diabetes type I and/or II, inadequate glucose tolerance, insulin resistance, hyperlipidemia, hypertriglyceridemia, hypercholesterolemia, obesity, polycystic ovary syndrome (PCOS). The compounds of this invention are particularly useful in the treatment of type II diabetes, obesity or the regulation of appetite. Specifically, the present invention is related to substituted methylene amide derivatives for the modulation, notably the inhibition of the activity of PTPs, in particular of PTP1B.

Background of the invention

The prevalence of insulin resistance in glucose intolerant subjects is well known. Reaven et al (*American Journal of Medicine*, 60, 80 (1976)) used a continuous infusion of glucose and insulin (insulin/glucose clamp technique) and oral glucose tolerance tests to demonstrate that insulin resistance exists in a diverse group of non-obese, non-ketotic subjects. These subjects ranged from borderline glucose tolerant to overt, fasting hyperglycemia. The diabetic groups in these studies included both insulin dependent (IDDM) and non-insulin dependent (NIDDM) subjects.

Coincident with sustained insulin resistance is the more easily determined hyperinsulinemia, which may be measured by accurate determination of circulating plasma insulin concentration in the plasma of subjects. Hyperinsulinemia may be present as a result of insulin resistance, such as is in obese and/or diabetic (NIDDM) subjects and/or glucose intolerant subjects, or in IDDM subjects, as a consequence of over injection of insulin compared with normal physiological release of the hormone by the endocrine pancreas.

The association of hyperinsulinemia and insulin resistance with obesity and with ischemic diseases of the large blood vessels (e.g. atherosclerosis) has been well established by numerous experimental, clinical and epidemiological studies (Stout, *Metabolism*, 34, 7 (1985)). Statistically significant plasma insulin elevations at 1 and 2 hours after oral glucose load correlate with an increased risk of coronary heart disease.

Since most of these studies actually excluded diabetic subjects, data relating the risk of atherosclerotic diseases to the diabetic condition are not as numerous, but point in the same direction as for non-diabetic subjects. However, the incidence of atherosclerotic diseases in morbidity and mortality statistics in the diabetic population exceeds that of the nondiabetic population (Pyorala et al; Jarrett *Diabetes/Metabolism Reviews*, 5, 547 (1989)).

The association of hyperinsulinemia and insulin resistance with Polycystic Ovary Syndrome (PCOS) is also well acknowledged (Diamanti-Kandarakis et al.; Therapeutic effects of metformin on insulin resistance and hyperandrogenism in polycystic ovary syndrome; *European Journal of Endocrinology* 138, 269-274 (1998), Andrea Dunaif; Insulin Resistance and the Polycystic Ovary Syndrome : Mechanism and Implications for Pathogenesis; *Endocrine Reviews* 18(6), 774-800 (1997)).

The independent risk factors obesity and hypertension for atherosclerotic diseases are also associated with insulin resistance. Using a combination of insulin/glucose clamps, tracer glucose infusion and indirect calorimetry, it was demonstrated that the insulin resistance of essential hypertension is located in peripheral tissues (principally muscle) and correlates directly with the severity of hypertension (DeFronzo and Ferrannini, *Diabetes Care*, 14, 173 (1991)). In hypertension of obese people, insulin resistance generates hyperinsulinemia, which is recruited as a mechanism to limit further weight gain via thermogenesis, but insulin also increases renal sodium re-absorption and stimulates the sympathetic nervous system in kidneys, heart, and vasculature, creating hypertension.

It is assumed that insulin resistance is usually the result of a defect in the insulin receptor signaling system, at a site post binding of insulin to the receptor. Accumulated scientific evidence demonstrating insulin resistance in the major tissues which respond to insulin (muscle, liver, adipose), strongly suggests that a defect in insulin signal transduction resides at an early step in this cascade, specifically at the insulin receptor kinase activity, which appears to be diminished (Mounib Elchebly, Alan Cheng, Michel L. Tremblay; Modulation of insulin signaling by protein tyrosine phosphatases; *J. Mol. Med.* 78, 473-482 (2000)).

Protein-tyrosine phosphatases (PTPs) play an important role in the regulation of phosphorylation of proteins and represent the counterparts of kinases. Among classical PTPs, there are two types : (i) non-receptor or intracellular PTPs and (ii) receptor-like PTPs. Most intracellular PTPs contain one catalytic domain only, whereas most receptor-like enzymes contain two. The catalytic domain consists of about 250 amino acids (Niels Peter Hundahl Moller et al. Protein tyrosine phosphatases (PTPs) as drug targets: Inhibitors of PTP-1B for the treatment of diabetes; *Current Opinion in Drug Discovery & Development* 3(5), 527-540 (2000)).

The interaction of insulin with its receptor leads to phosphorylation of certain tyrosine molecules within the receptor protein, thus activating the receptor kinase. PTPs dephosphorylate the activated insulin receptor, attenuating the tyrosine kinase activity. PTPs can also modulate post-receptor signaling by catalyzing the dephosphorylation of cellular substrates of the insulin receptor kinase. The enzymes that appear most likely to closely associate with the insulin receptor and therefore, most likely to regulate the insulin receptor kinase activity, include PTP1B, LAR, PTP-alpha and SH-PTP2 (Lori Klaman et *al.*; Increased Energy Expenditure, Decreased Adiposity, and Tissue-specific insulin sensitivity in Protein-Tyrosine Phosphatase 1B-Deficient Mice; *Molecular and Cellular Biology*, 5479-5489 (2000)).

PTP1B is a member of the PTP family. This 50 kDa protein contains a conserved phosphatase domain at residues 30-278 and is localized to the cytoplasmic face of the

endoplasmic reticulum by its C-terminal 35 residues. Its interactions with other proteins are mediated by proline-rich regions and SH2 compatible sequence. PTP1B is believed to act as a negative regulator in insulin signaling.

McGuire et al. (*Diabetes*, 40, 939 (1991)) demonstrated that non-diabetic glucose intolerant subjects possessed significantly elevated levels of PTP activity in muscle tissue vs. normal subjects, and that insulin infusion failed to suppress PTP activity as it did in insulin sensitive subjects.

Meyerovitch et al. (*J. Clinical Invest.*, 84, 976 (1989)) observed significantly increased PTP activity in the livers of two rodent models of IDDM, the genetically diabetic BB rat, and the STZ-induced diabetic rat. Sredy et al. (*Metabolism*, 44, 1074, (1995)) observed similar increased PTP activity in the livers of obese, diabetic ob/ob mice, which represent a typical rodent model of NIDDM.

Zhang et *al* (*Curr. Opin. Chem. Biol.*, 5(4), 416-23 (2001)) found that PTPs are also implicated in a wide variety of other disorders, including cancer. Bjorge, J.D. et *al.* (*J. Biol. Chem.*, 275(52), 41439-46 (2000)) indicates that PTP1B is the primary protein-tyrosine phosphatase capable of dephosphorylating c-Src in several human breast cancer cell lines and suggests a regulatory role for PTP1B in the control of c-Src kinase activity.

Pathre et al (*J. Neurosci. Res.*, 63(2), 143-150 (2001)) describes that PTP1B regulates neurite extension mediated by cell-cell and cell-matrix adhesion molecules. Further, Shock L. P et al. (*Mol. Brain. Res.*, 28(1), 110-16 (1995)) demonstrates that a distinct overlapping set of PTPs is expressed in the developing brain and retinal Mueller glia, including 2 novel PTPs that may participate in neural cell communication.

The insulin receptor (IR) is a prototypical tyrosine kinase receptor whose ligand binding and dimerization results in auto-phosphorylation on multiple tyrosines. This is followed by the recruitment and phosphorylation of IRS1-4 (depending on the tissue) and PI3K. Although vanadium-containing compounds have been known since the 19th century to

alleviate diabetes, it was understood only recently that these inhibitors stimulate the insulin signaling pathway by blocking PTP action. Evidence for the involvement of the IR (insulin receptor) and IRS-1 in this phenotype was that both proteins show increased tyrosine phosphorylation in the PTP1B-mutated mice. The available data strongly suggest that in particular PTP1B is a promising target for the development of drugs to treat diabetes and obesity (Brian P. Kennedy and Chidambaram Ramachandran; Protein Tyrosine Phosphatase-lB in Diabetes; *Biochemical Pharmacology*, Vol. 60, 877-883, (2000)).

A further protein involved in obesity is Leptin. Leptin is a peptide hormone that plays a central role in feeding and adiposity (*Leptin. Annu. Rev. Physiol.* **62** p.413-437 (2000) by Ahima R. S. et al.). Recently, it has been suggested that PTP1B negatively regulates leptin signaling, and provide one mechanism by which it may regulate obesity. Further, it is known that pharmacological inhibitors of PTP1B hold promise as an alternative or a supplement to leptin in the treatment of obesity due to leptin resistance (*Developmental Cell.*, **vol.2**, p.497-503 (2002)).

Several small molecules have been proposed as inhibitors of PTPs, among others WO 02/18321.

Compounds (III-4), wherein P is H, may be obtained by deprotection of their corresponding protected form, wherein P is a protecting group (e.g. Boc or Fmoc).

Compounds (III-4), wherein P is H or any protecting groups (e.g. Boc or Fmoc), may be prepared from their precursor of formula (III-4') and an alkyne of formula (XII) following protocols such as described in the Examples and shown in Scheme 4 (Method H).

A preferred process for preparing compounds of formula (III) is set out in the above Scheme 5, Method I. Therein, the reductive amination of carbonyl compounds of formula (IX) wherein Q is -COO-Bn is performed with amines of formula (IV) and a reducing agent such as $NaBH(OAc)_3$ in a suitable solvent such as DCE or THF. The process thus affords the amine of formula (III), wherein Q is C(O)OBn.

According to the methods described in Scheme 1 (Method A), the resulting amine (III) is coupled with an ester LG_2-CO-COO-R^8, wherein R^8 is a (C_1-C_6)alkyl or cycloalkyl, preferably ethyl or methyl, and LG_2 is a leaving group such as e.g. Cl, in the presence of a base such as DIEA in an aprotic solvent (such as e.g. DCM or THF), thus affording substituted methylene amide derivatives of formula (II-1). Subsequent benzyl deprotection using standard H_2/Pd methods and followed by the coupling of the resulting acid, wherein X is CO and LG_1 is -OBn, with amines -$NHR^3R^{3'}$, with using standard carbodiimide - or standard mixed anhydride - mediated methods affords the desired compounds of formula (I-1), wherein R^8 is ethyl or methyl (see Scheme 1). The latter compounds may be hydrolysed to yield compounds of formula (Ia) of this invention, wherein R^8 is H, by their treatment with hydroxide such as e.g. NaOH in an appropriate protic solvent (such as e.g. EtOH), followed by acidification of the reaction mixture.

According to a further preferred process of preparing compounds of formula (Ia), carbonyl derivatives of formula (IX) (see Scheme 5), wherein Q is -$CONR^3R^{3'}$ may be prepared from their commercially available or readily accessible from commercial starting materials precursor in which Q is -COOH and amines $HNR^3R^{3'}$ using standard carbodiimide- or standard mixed anhydride-mediated methods. Basic salts of the compounds of formula (I) are prepared in a conventional manner as is known by a person skilled in the art. g) Preparation using Solid-Phase and/or mixed solid/solution phase:

According to yet another general approach, substituted methylene amides according to the general formula (Ia), wherein the substituents R^1, R^{2a}, R^{2b} and Cy are as above defined, may be prepared by solid-phase and/or mixed solid/solution-phase synthesis protocols such as those described in the examples and shown in Schemes 1, 2, 3, 4, 5 and 6 above using well known technical approaches (such as IRORI®). It will be appreciated by the practitioner skilled in the art that basically the same conditions, methods and reagents as above described in Schemes 1, 2, 3 and 4 for the solution-phase synthesis of compounds of formula (Ia) could be applied to the solid-phase and/or mixed solid-/solution-phase synthesis of said compounds. In the context of such a solid-phase and/or mixed solid-solution-phase synthesis protocol, R^3 is as above-defined. Cleavage from the resin is effected under acidic conditions, affording the corresponding substituted methylene amide derivatives of formula (Ia). It is to be understood that further to the resin types mentioned in the Examples such as e.g. Sasrin aldehyde resins, other suitable reagents, notably resins,

known to a person skilled in the art, could be employed for the solid-phase synthesis of compounds of general formula (Ia).

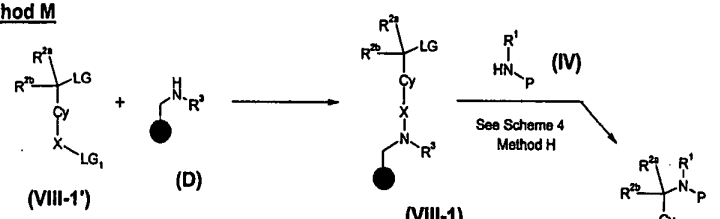
The filled circles in the below Scheme 6 illustrate the resin beads to which the compounds are linked during the solid phase synthesis.

In one particularly preferred process, resin-bound amines of formula NHR^3R^6 (D), wherein R^6 represents any suitable resin (Scheme 6) and R^3 is above-defined in the description, are prepared from commercially available *per se* or readily accessible from resins such as e.g. Sasrin aldehyde or bromo-Wang resins and amines, using standard reductive amination or alkylation conditions well known to the practitioner skilled in the art. The resin-bound amines NHR^3R^6 (D) may then be acylated with compounds of formula (VIII-1') wherein X is –CO- and LG_1 is Cl in the presence of base such as e.g. DIEA, in suitable solvent such as NMP or DCM; or X may also be is $-SO_2-$ and LG_1 is Cl using standard conditions involving a base such as DIEA in an aprotic solvent such as DCM or THF affording compounds of formula (VIII-1) (Scheme 6, Method N).

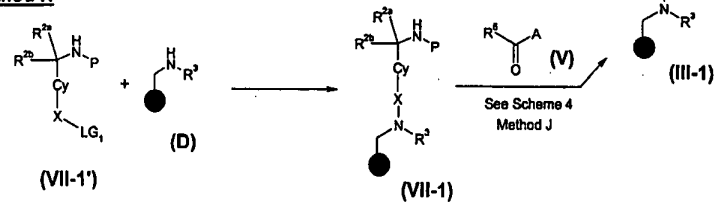
According to the methods outlined in Scheme 5 (Method J), the displacement of the leaving group LG from the latter resin-bound intermediates (VIII-1) by their reaction with amines $NHPR^1$ (IV) in the presence of iodide such as TBAI or NaI in a suitable solvent such as e.g. NMP at suitable temperature such as 80°C can afford resin-bound compounds of Formula (III-1). Finally, this compounds is coupled with the ester LG_2-CO-COO-R^8, wherein R^8 is preferably ethyl or methyl and LG_2 is a leaving group such as e.g. Cl, in the presence of a base such as DIEA in an aprotic solvent (such as e.g. DCM or THF) affording the resin-bound ester (I-1). The latter compounds can be hydrolysed to compounds of formula (Ia) of this invention, wherein R^8 is H, by their treatment with hydroxide such as e.g. NaOH in an appropriate solvent (such as e.g. THF). Cleavage from the resin is performed under acidic conditions (such as e.g. a DCM solution containing 20 % TFA), affording the corresponding desired substituted methylene amide derivatives of Formula (Ia).

Scheme 6

Method M



Method N



In one other preferred synthetic approach (Method N), the resin-bound amines of formula NHR^6R^3 (D), wherein R^6 represents a suitable resin (Scheme 6) can be acylated with compounds of formula (VII-1'), wherein X is -CO-, LG_1 is OH, R^1, R^{2a}, R^{2b}, R^3 and R^5 are as above-defined and P is a protecting group such as Fmoc or Pht, using standard conditions involving a coupling reagent such as e.g. PyBOP®, in a suitable solvent such as NMP or DCM affording resin-bound compounds of formula (VII-1). The same resin-bound amines of formula NHR^6R^3 can be sulfonylated with compounds of formula (VII-1'), wherein X is $-SO_2-$, LG_1 is Cl and P is a protecting group such as Fmoc or Pht, using standard conditions involving a base such as DIEA affording resin-bound compounds of formula (VII-1). These latter intermediates can be deprotected following standard conditions and then alkylated following the methods outlined in Scheme 5 (Method H) to afford the compounds of formula (III-1). Finally, these compounds are converted to the desired substituted methylene amides of formula (Ia), following the methods described above.

When employed as pharmaceuticals, substituted methylene amide derivatives of the present invention are typically administered in the form of a pharmaceutical composition. Hence, pharmaceutical compositions comprising a compound of formula (I) and a pharmaceutically acceptable carrier, diluent or excipient therefore are also within the scope of the present invention. A person skilled in the art is aware of a whole variety of such carrier, diluent or excipient compounds suitable to formulate a pharmaceutical composition.

The compounds of the invention, together with a conventionally employed adjuvant, carrier, diluent or excipient may be placed into the form of pharmaceutical compositions and unit dosages thereof, and in such form may be employed as solids, such as tablets or filled capsules, or liquids such as solutions, suspensions, emulsions, elixirs, or capsules filled with the same, all for oral use, or in the form of sterile injectable solutions for parenteral (including subcutaneous use). Such pharmaceutical compositions and unit dosage forms thereof may comprise ingredients in conventional proportions, with or without additional active compounds or principles, and such unit dosage forms may contain any suitable effective amount of the active ingredient commensurate with the intended daily dosage range to be employed.

When employed as pharmaceuticals, substituted methylene amide derivatives of this invention are typically administered in the form of a pharmaceutical composition. Such compositions can be prepared in a manner well known in the pharmaceutical art and comprise at least one active compound. Generally, the compounds of this invention are administered in a pharmaceutically effective amount. The amount of the compound actually administered will typically be determined by a physician, in the light of the relevant circumstances, including the condition to be treated, the chosen route of administration, the actual compound administered, the age, weight, and response of the individual patient, the severity of the patient's symptoms, and the like.

The pharmaceutical compositions of these inventions can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular, and

intranasal. The compositions for oral administration can take the form of bulk liquid solutions or suspensions, or bulk powders. More commonly, however, the compositions are presented in unit dosage forms to facilitate accurate dosing. The term "unit dosage forms" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical excipient. Typical unit dosage forms include prefilled, premeasured ampoules or syringes of the liquid compositions or pills, tablets, capsules or the like in the case of solid compositions. In such compositions, the substituted methylene amide derivative according to the invention is usually a minor component (from about 0.1 to about 50% by weight or preferably from about 1 to about 40% by weight) with the remainder being various vehicles or carriers and processing aids helpful for forming the desired dosing form.

Liquid forms suitable for oral administration may include a suitable aqueous or nonaqueous vehicle with buffers, suspending and dispensing agents, colorants, flavors and the like. Solid forms may include, for example, any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatine; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, or corn starch; a lubricant such as magnesium stearate; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring.

Injectable compositions are typically based upon injectable sterile saline or phosphate-buffered saline or other injectable carriers known in the art. As above mentioned, substituted methylene amide derivatives of formula (I) in such compositions is typically a minor component, frequently ranging between 0.05 to 10% by weight with the remainder being the injectable carrier and the like.

The above described components for orally administered or injectable compositions are merely representative. Further materials as well as processing techniques and the like are

set out in Part 8 of *Remington's Pharmaceutical Sciences*, 17th Edition, 1985, Marck Publishing Company, Easton, Pennsylvania, which is incorporated herein be reference.

Step a) Formation of tert-Butyl-3-bromo benzoate

To a mixture of 3-bromo benzoic acid (100g, 0.5 mol), silver carbonate (276g, 1mol) and dry molecular sieves (100 g) taken in dry CH_2Cl_2 (2 L), *tert*-butylbromide (115mL, 1mol) was added dropwise at 0°C and the reaction mixture was stirred overnight at RT. The solid was filtered and washed with dichloromethane. Organic layer was washed with 10 % aqueous solution of $NaHCO_3$ (2x 500mL), water(2x 500 mL), brine and dried. The solvent was removed under vacuum to give *tert*-butyl-3-bromobenzoate (70g, 57 %).

Step b) Formation of tert-butyl-3-(4-tolyl) bromobenzoate

To a mixture of *tert*-butyl-3-bromobenzoate (65 g, 0.25 mol), 4-tolyl boronic acid (41.3 g, 0.30 mol) and sodium carbonate (150g) in a mixture of toluene (500mL) and water (50 mL), tetrakis-triphenylphosphine palladium(0) (14.5 g, 0.05 mol) was added and the reaction mixture was refluxed overnight. Cooled to RT, toluene layer was separated. The organic layer was washed with water, brine, dried. The solvent was removed under vacuum to give *tert*-butyl-3-(4-tolyl)benzoate (62 g, 90 %).

Step c) Formation of 4-(3-tert-butoxy carbonyl phenyl) benzyl bromide

A solution of 4-(3-carboxyphenyl)benzylamine hydrochloride (20 g, 0.075 mol) in 10 % Na_2CO_3 (350 mL) and dioxane (100 mL) was cooled to 0°C with stirring. A solution of Fmoc-OSu (30.7 g, 0.091 mol) in dioxane (100 mL) was added in one portion and the reaction mixture was stirred at RT for 3h. Acidified with 1.5 N aqueous solution of HCl and extracted with EtOAc (3x 400 mL). The organic layer was washed with water (3x 500 mL), brine dried over Na_2SO_4 and concentrated, purification by column chromatography using dichloromethane/methanol (9:1) to give *N*-Fmoc-4-(3-carboxyphenyl)benzylamine (16 g). The organic layer was washed with an aqueous solution of $NaHCO_3$ (10 %), water, brine, dried and concentrated to give *tert*-butyl-4-bromobenzoate (90 g, 71 %).

Step b) Preparation of tert-butyl-4-(4-tolyl)benzoate

To a mixture of *tert*-butyl-4-bromobenzoate (40 g, 0.15 mol), 4-tolylboronic acid (23.3 g, 0.17 mol) and sodium carbonate (150 g) in toluene (350 mL) and water (350 mL) was added tetrakis(triphenylphosphine) palladium(0) (8.7 g, 0.007 mol) and the reaction mixture was refluxed for 10 h under nitrogen atmosphere. The organic layer was separated, washed with water, dried and concentrated to give *tert*-butyl-4-(4-tolyl) benzoate (32 g, 77 %).

Step c) Preparation of 4-(4-tert-butoxycarbonyl phenyl) benzyl bromide

To a solution of tert-butyl-4-(4-tolyl)benzoate (32 g, 0.12 mol) in carbontetrachloride (500 mL) was added *N*-bromosuccinimide (23.3 g, 0.13 mol) and benzoyl peroxide (4.0 g). The reaction mixture was refluxed for 10 h. After cooling to RT, the reaction mixture was filtered. The filtrate was concentrated and the crude was recrystallised from petEther to give 4-(4-*tert*-butoxycarbonylphenyl) benzylbromide (26 g, 69 %).

Step d) Preparation of 4-(4-Carboxyphenyl)benzylamine hydrochloride

To a solution of 4-(4-*tert*-Butoxycarbonyl)benzylbromide (25 g, 0.071 mol) in methanol (2 L), cooled to –20°C was passed through the reaction mixture ammonia for 5 h. The reaction mixture was stirred at RT for 30 h. Methanol was removed under vacuum. To the residue

an aqueous solution of HCl (6N, 200 mL) was added and stirred at RT overnight. The solvents were evaporated under vacuum and the resulting residue was washed with diethyl ether to give 4-(4-carboxyphenyl)benzylamine hydrochloride (10 g, 53 %).

Step e) Preparation of N-Fmoc-4-(4-carboxyphenyl)benzylamine

4-(4-Carboxyphenyl)benzylamine hydrocloride (10 g, 0.038 mol) was taken in a mixture of 10% Na_2CO_3 (100 mL) and dioxane (25 mL). To this a solution of Fmoc-OSu (15.4 g, 0.045 mol) in dioxane (50 mL) was added at 10°C and the reaction was stirred at RT for 4 h. Solvent was removed under reduced pressure and the residue was acidified with an aqueous solution of HCl (1.5 N), extracted with EtOAc and the crude was recrystallised from EtOAc to give *N*-Fmoc-4-(4-carboxyphenyl)benzylamine (8.5 g, 45 %).

Step a) Preparation of methyl 4-methyl-1-naphthoate

To a stirred solution of 4-methyl-1-naphthoic acid (25 g, 0.13 mol) in methanol (350 mL), thionylchloride (39g, 0.33 mol) was added and the reaction mixture was refluxed for 15 h. Excess of thionylchloride and methanol was distilled off. The residue was taken up in DCM (400 mL), washed with an aqueous solution of $NaHCO_3$ (10%), water, brine and dried over $MgSO_4$. The solvent was removed under vacuum to give 4-methyl-1-naphthoic acid methyl ester (22.5 g, 83%) as pale yellow solid.

Step b) Preparation of methyl 4-(bromomethyl)-1-naphthoate

To a stirred solution of methyl 4-methyl-1-naphthoate (22.5 g, 0.112 mol) in CCl_4 (500 mL) was added NBS (22 g, 0.123 mol) and benzoylperoxide (10% w/w). The reaction mixture was allowed to reflux at 80°C for 7 h. The reaction mixture was cooled to rt and

filtered off. The solid and concentrated under vacuum and the obtained crude product (30 g) was used for further reaction.

Step c) Preparation of methyl 4-(azidomethyl)-1-naphthoate

Then the reaction mixture was diluted with water (500 mL), extracted with EtOAc (2x 250 mL), washed with water, brine and dried over $MgSO_4$. The solvent was removed under vacuum to give methyl 4-(azidomethyl)-1-naphthoate (20 g, 77%).

Step d) Preparation of methyl 4-(aminomethyl)-1-naphthoate hydrochloride

The reaction mixture was stirred at rt for 4 h then concentrated under vacuum, extracted with EtOAc (350 mL). The combined organic layers were washed with brine, dried over $MgSO_4$ and the solvent was removed under vacuum. The resulting residue was taken up in an aqueous solution of HCl (75 mL, 2N), washed with diethylether (2x 150 mL). The aqueous layer was treated with an aqueous solution of $NaHCO_3$ (10%) until pH 7. The mixture was then extracted with ethylacetate (2x 150 mL), washed with brine, dried over $MgSO_4$ and concentrated. The product was slowly added to a saturated solution of HCl (g) in diethyl ether (75 mL) and filtered off the solid hydrochloride product. The product was washed with dry ether (2x 100 mL) to give methyl-4-(aminomethyl)-1-naphthoate hydrochloride (5.5 g). Example 416 : Biological assays

The compounds of formula (I), may be subjected to the following assays :

(1) The PTP Enzyme Assay

(2) The in vivo assay in db/db mice

(1) **The PTP Enzyme Assay (in vitro assay)**

Assays for the determination of the PTP inhibitory activity of test compounds are well known to a person skilled in the art. An example of such an assay is described below :

The PTP Enzyme Assay aims at determining the extent of inhibition of PTPs, e.g. of PTP1B, SHP-1, SHP-2 or GLEPP-1 in the presence of a test compound of formula (I). The inhibition is illustrated by IC_{50} values which denote the concentration of test compound necessary to achieve an inhibition of 50% of said PTP's using the following concentration of the PTP substrate DiFMUP :

- 5 μM DiFMUP for PTP1b;
- 20 μM DiFMUP for SHP-1 and SHP-2;
- 30 μM DiFMUP for GLEPP-1.

a) PTPs cloning

The cloning and expression of the catalytic domain of PTP1B, may be performed as described in *J. Biol. Chem. 2000*, 275(13), pp 9792-9796.

b) Materials and Methods

The DiFMUP assay allows to follow the dephosphorylation of DiFMUP (6,8-DiFluoro-4-MethylUmbelliferyl Phosphate) - which is the PTP substrate – mediated by PTP into its stable hyrolysis product, i.e. DiFMU (6,8-difluoro-7-hydroxy coumarin). Due to its rather

low pKa and its high quantum yield, DiFMU allows to measure both acidic and alkaline phosphatase activities with a great sensitivity.

Assays were performed in a 96 well plate format, using the catalytic core of a human recombinant PTP as the enzyme and 6,8-DiFluoro-4-MethylUmbelliferyl Phosphate (DiFMUP, Molecular Probes, D-6567) as a substrate. Compounds to be tested were dissolved in 100% DMSO at a concentration of 2 mM. Subsequent dilutions of the test compounds (to yield a concentration of 100, 30, 10, 3, 1,0.3, 0.1, 0.03, 0.01, 0.001 µM) were performed in 100 % DMSO using a Tecan Stand Alone Workstation. 5 µl of diluted compound or vehicle (100% DMSO = control) was distributed to a black Costar 96 well plate. 25µl of DiFMUP diluted in the assay buffer (20mM Tris HCl pH 7.5, 0.01% IGEPAL CA-630, 0.1mM ethylenediaminetetracetic acid, 1mM DL-Dithiothreitol) were added, followed by 20µl of human recombinant PTP enzyme diluted in assay buffer in order to start the enzymatic reaction. Alternatively, 20µl of human recombinant PTP enzyme diluted in assay buffer can be added to the dilutions of compound or vehicule (distributed to a black Costar 96 well plate), followed by 25µl of DiFMUP diluted in the assay buffer. The reaction ran for 30 minutes at room temperature before reading the fluorescence intensity (integral or intensity) on a Perkin-Elmer Victor 2 spectrofluorimeter (excitation of 6,8-difluoro-7-hydroxy coumarin is at 355nm, the emission at 460 nm, for 0.1s). The percentage of inhibition is determined by measuring the relative fluorescence ion absence of a test compound (PTP inhibitor), i.e. with the solvent alone (5% DMSO). The IC_{50} values for inhibition were determined in triplicates.

The tested compounds according to formula (I) display an inhibition (illustrated by IC_{50} values) with regard to PTP of preferably less than 10 µM, more preferred less than 5 µM.

For instance, the compound of example 10 displays an IC_{50} value of 2.224 µM in respect of PTP1B, an IC_{50} value of 1.40 in respect of GLEPP-1, an IC_{50} value of 2.40 and 2.70 in respect of SHP-1 and SHP-2.

The compound of example 4 displays an IC_{50} value of 0,916 µM in respect of PTP1B and an IC_{50} value of 0.50 in respect of GLEPP-1, an IC_{50} value of 1 and 1.4 in respect of SHP-1 and SHP-2.

(2) <u>In vivo assay in db/db mice</u>

The following assay aims at determining the anti-diabetic effect of the test compounds of formula (I) in a model of postprandial glycemia in db/db mice, *in vivo*.

The assay was performed as follows :

A total of 24 db/db mice (about 8-9 weeks; obtained from IFFACREDO, l'Arbreste, France) were fasted during 20 hours.

4 groups, each consisting of 6 animals were formed :

Group 1 : The animals were administered (*per os*) a dose of 10 mg/kg of vehicle.

Group 2 : The animals were administered (*per os*) a dose of 20 mg/kg of the test compound according to formula (I).

Group 3 : The animals were administered (*per os*) a dose of 100 mg/kg of the test compound according to formula (I).

Group 4 : The animals were administered (*per os*) a dose of 200 mg/kg of the test compound according to formula (I).

After oral administration of the compounds of formula (I) solubilized or suspended in CarboxyMethylCellulose (0.5%), Tween 20 (0.25%) and water as vehicle, the animals had access to commercial food (D04, UAR, Villemoisson/Orge, France) *ad libitum*. The diabetic state of the mice was

verified by determining the blood glucose level before drug administration. Blood glucose and serum insulin levels were then determined 4 hrs after drug administration.

The determination of the blood glucose level was performed using a glucometer (Precision Q.I.D., Medisense, Abbot, ref. 212.62.31).

The determination of the Insulin level was performed using an ELISA kit (Crystal CHEM, Ref. INSK R020).

Changes in blood glucose and serum insulin of drug treated mice were expressed as a percentage of control (group 1: vehicle treated mice).

Treatment (*per os*) of the animals with substituted methylene amide compounds of formula (I), at a dosage of 50 mg/kg, decreased the blood glucose level induced by food intake by about 20-40%.

For instance, upon using the compound of example 10, i.e. {4-[(dodecylamino)carbonyl]-benzyl}[4-(trifluoromethyl) benzyl]amino}(oxo)acetic acid, the following decrease in blood glucose level as well as insulin level was determined :

Animal Group	Decrease in blood glucose	± SEM	Decrease in serum insulin	± SEM
Group 2	17	6	-2	7
Group 3	42	6	66	8
Group 4	48	4	89	2

(SEM = Standard Error of the Means)

(II-1)

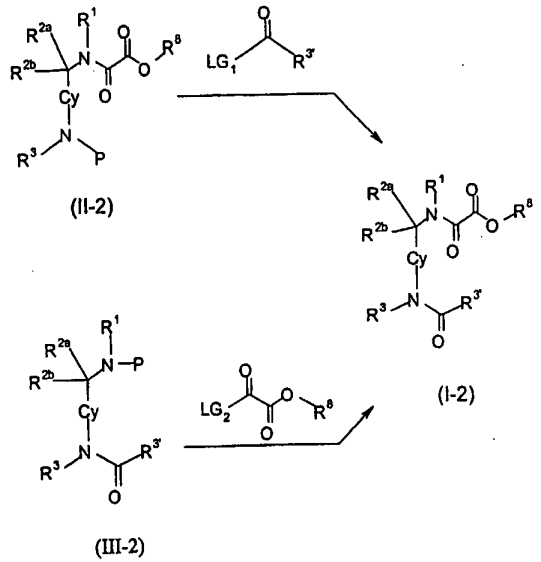
(I-1)

(III-1)

wherein X is –CO- or –SO_2-, LG_1 is Cl, OH, -Obn, O-Alkyl or O-Alkylaryl and LG_2 is selected from Cl, N-hydroxy succinimide or benzotriazol-1-yl, R^8 is a (C_1-C_6)alkyl or cycloalkyl, P is H or a protective group selected from Boc or Fmoc, R^1, R^{2a}, R^{2b}, R^3 and $R^{3'}$ are as above defined;

and a subsequent hydrolysis step thus yielding the methylene amide derivative of formula (I).

32. A method of preparing a substituted methylene amide derivative of formula (I) according to any of claims 1 to 5, 9 to 11, 14 and 15 comprising the step of providing the corresponding ester of formula (I-2):



(II-2)

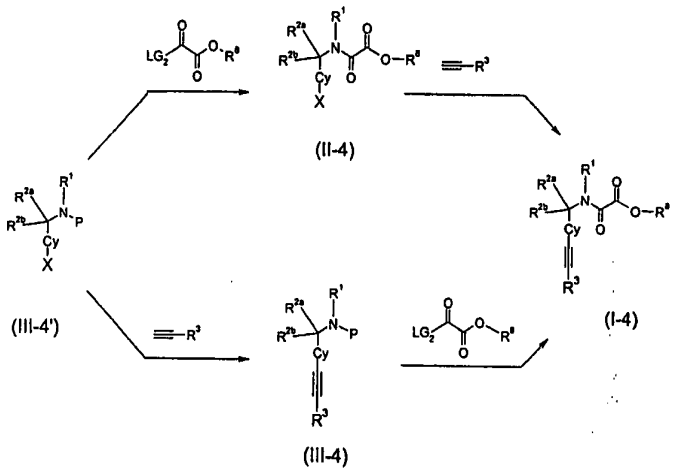
wherein LG_1 is Cl, OH, OBn, O-Alkyl or O-Alkylaryl and LG_2 is selected from Cl, N-hydroxy succinimide or benzotriazol-1-yl, R^8 is a C_1-C_6 alkyl or cycloalkyl, P is H or a protective group selected from Boc or Fmoc, R^1, R^{2a}, R^{2b}, R^3 and $R^{3'}$ are as above defined;

and a subsequent hydrolysis step, thus yielding the methylene amide derivative of formula (I).

33. A method of preparing a substituted methylene amide derivative according to any of claims 1 to 11 and 15 , comprising the step of providing the corresponding ester of formula (I-4):



wherein X is halogen atom selected from the group consisting of Br, I Cl or a leaving group such as $-OSO_2CF_3$, R^8 is an alkyl group, LG_2 is selected from Cl, N-hydroxy succinimide or benzotriazol-1-yl, P is H or a protective group selected from Boc or Fmoc, R^1, R^{2a}, R^{2b} and R^3 are as above defined;

and a subsequent hydrolysis step, thus yielding the methylene amide derivative of formula (I).
